Model Provider Architecture

Figure 1: Model Provider Architecture

Overview

The model provider layer is a clean abstraction that isolates the agent loop from LLM-specific API details. Every provider implements the same `Model` ABC, so swapping backends is a one-line configuration change.

Abstract Interface: `Model`

```python
class Model(ABC):
    def update_config(self, **model_config: Any) -> None: ...
    def get_config(self) -> Any: ...

    def stream(
        self,
        messages: Messages,
        tool_specs: list[ToolSpec] | None = None,
        system_prompt: str | None = None,
        *,
        tool_choice: ToolChoice | None = None,
        system_prompt_content: list[SystemContentBlock] | None = None,
        invocation_state: dict[str, Any] | None = None,
    ) -> AsyncIterable[StreamEvent]: ...

    def structured_output(
        self,
        output_model: type[T],
        prompt: Messages,
```

```
        system_prompt: str | None = None,
    ) -> AsyncGenerator[dict[str, T | Any], None]: ...
```

`stream()` — The Core Method

Each provider must implement `stream()` which:

1. **Formats** the request — converts the common `Messages`, `ToolSpec`, and `SystemContentBlock` types into the provider's native API format
2. **Sends** the request to the LLM API (streaming)
3. **Yields** normalised `StreamEvent` chunks back to the event loop

The last event yielded contains a `"stop"` key with: - `stop_reason: StopReason` — why the model stopped (`end_turn`, `tool_use`, `max_tokens`) - `message: Message` — the full assistant message with text and/or tool use blocks - `usage: Usage` — token counts (input, output, cache read/write) - `metrics: Metrics` — latency in milliseconds

`structured_output()` — Typed Responses

Processes prompts and returns Pydantic model instances. Implementations typically: 1. Add the output schema to the prompt 2. Call the model 3. Parse the response into the Pydantic model 4. Raise `ValidationException` if parsing fails

Supported Providers

Provider	File	Default Model	Notes
Amazon Bedrock	`bedrock.py`	`us.anthropic.claude-sonnet-4-20250514`	SDK default, uses boto3
Anthropic	`anthropic.py`	—	Direct Anthropic API
OpenAI	`openai.py`	—	Chat completions
OpenAI Responses	`openai_responses.py`		Responses API variant
Google Gemini	`gemini.py`	—	Google AI Studio
Ollama	`ollama.py`	—	Local models via Ollama
llama.cpp	`llamacpp.py`	—	Direct GGUF inference
LlamaAPI	`llamaapi.py`	—	Hosted Llama models
Mistral	`mistral.py`	—	Mistral AI API
Writer	`writer.py`	—	Writer API
SageMaker	`sagemaker.py`	—	Custom SageMaker endpoints
LiteLLM	`litellm.py`	—	Meta-router for 100+ providers
Cohere	(community)	—	Via community contributions

Provider Implementation Pattern

Every concrete provider follows the same structure:

```
1. __init__(client_args, model_id, params)
   → Create API client with credentials
   → Store model configuration

2. stream(messages, tool_specs, system_prompt)
```

```
→ format_request(messages, tool_specs, system_prompt)
  → Convert Messages to provider's message format
  → Convert ToolSpec to provider's function/tool format
  → Build the API request body
→ send_request(request)
  → Call provider's streaming API
→ process_stream(response)
  → Parse each chunk into StreamEvent
  → Build up the full Message from chunks
  → Yield final stop event with (stop_reason, message, usage, metrics)
```

Key Types

```python
# Common message format
Message = TypedDict("Message", {"role": str, "content": list[ContentBlock]})
Messages = list[Message]

# Tool specification sent to models
ToolSpec = TypedDict("ToolSpec", {
    "name": str,
    "description": str,
    "inputSchema": dict  # JSON Schema
})

# Token usage
Usage = TypedDict("Usage", {
    "inputTokens": int,
    "outputTokens": int,
    "totalTokens": int,
    "cacheReadInputTokens": NotRequired[int],
    "cacheWriteInputTokens": NotRequired[int],
})

# Tool choice control
ToolChoice = TypedDict with "auto", "any", or "tool" key
```

Prompt Caching

The `CacheConfig` dataclass enables prompt caching: - `strategy: "auto"` — automatically inject `cachePoint` markers at optimal positions - Supported via `system_prompt_content: list[SystemContentBlock]` parameter

Error Handling

- `ModelThrottledException` — raised when the provider returns a rate-limit error; caught by the event loop's retry strategy
- Provider-specific errors are wrapped or re-raised as appropriate
