End-to-End Data Flow

Figure 1: Data Flow

Complete Flow of a Single Invocation

This traces what happens when you call `agent("What's the weather in London?")`:

Step 1: User Input

```
result = agent("What's the weather in London?")
```

- `__call__` → `invoke_async` → `stream_async` → `_run_loop`
- The prompt string is converted to `Message(role="user", content=[{"text": "..."}])`
- Appended to `agent.messages`

Step 2: BeforeInvocationEvent

- `SessionManager.initialize()` restores previous session if available
- Guardrails or PII redaction hooks can modify `event.messages`
- Any setup/validation logic runs here

Step 3: Model Inference

- `BeforeModelCallEvent` fires
- `stream_messages()` calls `model.stream(messages, tool_specs, system_prompt)`
- The model sees the full conversation + available tools
- Streaming chunks are yielded back as events
- `AfterModelCallEvent` fires — can trigger retry on throttle

Step 4: Response Routing

The model's `stop_reason` determines the next step: - `"end_turn"` → the model has a final answer, skip to Step 8 - `"tool_use"` → the model wants to call tool(s), proceed to Step 5 - `"max_tokens"` → response was truncated, raise `MaxTokensReachedException`

Step 5: Tool Execution

For each `ToolUse` block in the assistant's message: 1. `BeforeToolCallEvent` fires — hooks can cancel, interrupt, or modify 2. The tool's `stream()` method executes with the provided inputs 3. `AfterToolCallEvent` fires — hooks can modify the result or retry

Multiple tools may execute concurrently (default) or sequentially.

Step 6: Tool Results → Messages

- Each tool result is wrapped as `{"toolResult": {"toolUseId": "...", "status": "success", "content": [...]}}`
- A single `Message(role="user", content=[...all tool results...])` is built
- Appended to `agent.messages`
- `MessageAddedEvent` fires → session manager persists

Step 7: Recurse

Unless `request_state["stop_event_loop"]` is set, the event loop recurses: - `recurse_event_loop()` starts a new cycle - The model now sees the tool results in the conversation - Back to Step 3

Step 8: Final Response

- `EventLoopStopEvent` is yielded with the final message
- `AfterInvocationEvent` fires → session manager syncs final state
- Metrics are finalized

Step 9: AgentResult Returned

```
AgentResult(
    stop_reason="end_turn",
    message={"role": "assistant", "content": [{"text": "It's currently 12°C..."}]},
    metrics=EventLoopMetrics(...),
    state={...},
    interrupts=None,
    structured_output=None,
)
```

Typical Cycle Count

Scenario	Cycles
Simple Q&A (no tools)	1
Single tool call	2 (model → tool → model)
Multi-step reasoning	3-5
Complex research task	5-10+

Message History Growth

After a 2-cycle invocation with one tool call:

```
messages = [
  {"role": "user", "content": [{"text": "What's the weather?"}]},           # User input
 {"role": "assistant", "content": [{"toolUse": {"name": "weather", ...}}]}, # Model requests tool
  {"role": "user", "content": [{"toolResult": {"status": "success", ...}}]}, # Tool result
  {"role": "assistant", "content": [{"text": "It's 12°C in London..."}]},    # Final answer
]
```

Streaming Events

Callers using `stream_async()` receive a stream of typed events throughout execution:

```
async for event in agent.stream_async("What's the weather?"):
    if "data" in event:           # Text chunk from model
        print(event["data"], end="")
    elif "tool_use" in event:     # Tool being called
        print(f"Calling {event['tool_use']['name']}...")
    elif "tool_result" in event:  # Tool completed
        print(f"Got result")
```

This enables real-time UIs that show the agent's progress as it works.
